cognitive style test

(the ways of coping)

Summary of research

Burns are very frequent traumatic pathology which his mechanisms and risk factor are not very well known such as skin cancers on burns scars which are one of the most dangerous complication of this disease the associated victims and mortality consequent to this phenomenon continues to be a source of preoccupation of this study.

To review the most strategic perfected by the patients to cope with this situation , and its relation to style of thinking according to kin of burns (external and internal burns) and sex.

The study include a sample of 40 patients, the relation was evaluated by the use of two questionnaires (cognitive style test, and the ways of coping).

The following hypotheses have been formulated in order to answer the different questions posed by this research.

- 1- coping being behavior or coping is expected to be different in accordance with the style of thinking used by the patients
- 2- the use of coping strategies is expected to be different due to the kind of burns

- 3- the style of thinking is expected to be different due to the kind of burns
- 4- the use of coping strategies is expected to be different due to the sex differences
- 5- the style of thinking is expected to be different due to differences in sex

the results achieved proved that the style of thinking for the patients was proved positive with solving problems strategy and was proved negative for the other coping strategies.

The result also showed for each variable that the style of thinking and the use of coping strategy (unless positive reevaluation strategy)is not different between the two sexes , and for both kinds of burns.

Finally, the study tries to make some suggestions and recommendations, that is believed are essential to prevent or reduce the adverse consequences of pain not only at the physiological level but also at the psychological one.
